```

[00:00:01] Speaker1:
Hey everyone Marcus here. I'm going to keep this short because I know your time is super valuable But I had to record this myself Because what I'm hearing from customers right now is too good to not directly share with you Since we launched cloud control last week customer response has been remarkable I'd say super remarkable one customer told me this is the first Cisco product that felt like it was built for the operator Not the engineer that stopped me cold. That's kind of feedback that tells you we built something real So we're talking about ICP qualification, this is where I need you to be the filter, and this is where I need your help. We have really, really strong momentum, and we want each one of these early customers

[00:00:42] Speaker2:
to have a great experience.

[00:00:43] Speaker1:
So we have a clear, ideal customer profile for cloud control. I need each of you to know what code and use it as your compass for every customer conversation. Ask the right questions early. Does this customer meet the regional and environment they fit? Are they struggling with visibility and control across their infrastructure? Do they have the operational maturity to move quickly? If the answer is yes, accelerate hard. If the signals aren't there, that's okay too. Continue to nurture as the platform evolves. You are the most trusted technical voice in the room with our customers. Your qualification instincts matter more than anything else. And look, DeCloud is your secret weapon. Now, I need every one of you to get into DeCloud. this week. We have a world-class demo environment built specifically for you, it's ready, it isn't a placeholder, it's polished, it's powerful, and it tells the Cisco Cloud Control story better than any slide deck ever could. Book the time, walk through the full demo, get comfortable with the flow so that when you're in front of a customer, you're not presenting, you're showing them the future. Now look, we have the right product, we're in the right market window, and we have the best SE community in the industry. I believe that completely. Stay sharp on the ICP, master

the demo and keep sharing what you're hearing in the field because your feedback is making this product better every single day. Thank you for what you do. Now let's go show what customers as possible. Thanks all. All right.

[00:02:24] Speaker2:
That was a great message for us. I'm going to be from here and I will go straight into Cloud Control, very quick introduction. My name is Amit Dutta. I'm one of the product management directors in Cloud Control.

[00:02:39] Speaker1:
I lead the platform.

[00:02:41] Speaker2:
And let me quickly go ahead and share my screen

[00:02:47] Speaker1:
and presentation. And I also have Rajat with me. Hello, everyone. Rajat. Yeah, thanks. Thanks, Amit. Rajat Gulatti, Director of Product Management for AI Canvas and Unified AI Assistant. So nice to be here. Thank you for the opportunity to present and let's get started. Awesome.

[00:03:14] Speaker2:
All right, thank you. All right, so the way we have divided this very quickly. So I'm going to, out of it, Cloud Control, provide some deep dive information and a quick demo and then we'll continue to demo with Rajat into AI Canvas and then provide some deep information on Canvas as well.

[00:03:37] Speaker2:
All right, so we'll start with the overview and one of the things that we wanted to kind of just start off with was primarily the system portfolio priorities. And you have seen this earlier as well. We are from a Cisco perspective working on the IIT data centers, feature proof workplaces and digital religion residents and everything is accelerated by Cisco AI. And so here is something that Cloud Control is embracing fully. So these are the use cases that we will have to support and resolve and Cloud Control provides that foundation. So that's where we're just going to stop there. OK, so I was assuming that you've already seen. So we are not going to go over the high level use cases. So we'll go a little bit deep today. So just to very quick recap, there are three major use cases that Cloud Control and AI Canvas is trying to solve for. So the first one is we have built a lot of depth in our vertical solutions in our domains. The connective tissue is missing, and Cloud Control aims to create that connective tissue. We have heard this from our customers multiple times. And what that means, it primarily means that being the front door to all our products, so you come into cloud control, you get access to your Cisco portfolio. So that's number one. The second was providing platform services and certain, I would say, capabilities within the platform, which allows for operation, day-to-day operations to be easier for our customers, and then providing the agenting operation surface, which is then surface by canvas for deeper troubleshooting and multiplayer collaborative experience, right? So those were kind of the three use cases that we like very highly will use cases we started with. So let's start off with the platform. So the platform, this is where most of the

foundation has been built on. On the left hand side, what you're seeing are the products which are already integrated today in control availability, as we know cloud control is already in CA, it was launched in Cisco Live. And all of these are already connected today, which means you can utilize any of these platforms to come onto Cloud Control, log into Cloud Control and start using it. I'll not go through all of them, but primarily all of the major controller and the domain architectures are already available, right? And we have also integrated with IQ. So we're cross launching into IQ as well to support. There is different, there's still work on going there for deeper integration, but we have connected it, let's put it that way. And then from the platform services perspective, the platform provide few things. So these are out of the box. If you get long control, you will get access to all of the services and it will go through most of these. So you get a singular identity, the platform. So there is a backend service called a Cisco Unified Identity. It allows for when a user logs into the platform for seamless movement between different platforms rather than doing multiple logins. So it's beyond, it's what I said. So it's actually a lot of the token. So this is basically done through tokens. So we utilize CUI tokens in which the other systems understand and it allows us to not only transfer identity but also transfer context. That's which is why RBAC for example, is very easily managed. we honor the RBAC in the product and the token provides us with that context so that we don't do any kind of privilege excavation. So we'll talk about that a little more. Then of course, full inventory is provided. The inventory is connected across all of our controllers and all the inventory is in one place. Same thing for topology, topology is end to end. Right now in control availability, we are providing the physical and the end to topology. We will be working on the L3 as we talk.

[00:07:58] Speaker2:
But it's one of those first time where you can see an end to a fully connected topology inside the network across multiple controller types across multiple domains all stitched together. We are also providing alerts and notifications. So this alerts are coming from all our controllers. We do correlation on those alerts to provide if they're in the same balance going from the controller we can kind of plug them to it, show it to the customer. And alerts is one of our job points into Canvas. So you look at an alert and you want to troubleshoot. That's where you generally will start with Canvas. And then there is licensing. We provide licensing information. Now, we are showing some forward-looking information here as well. Some of the things that you're seeing, like for example, the Cloud Control Studio, it got launched in CL, but it's still not available. It's still in the works. It's in alpha. But the CloudNATO Studio provides a marketplace, an agent builder and an app builder. And this is what the future is going to look like, particularly for operations standpoint. We'll talk a little bit about it. And the CloudNATO Studio obviously is powered by the agentic backend and the AI models which are providing powering of the agentic backend, which obviously is visualized through AI Canvas and AI Assistant. AI Canvas being the collaborative workspace where you troubleshoot where you learn more about your network, very, very generative, very intuitive, flexible troubleshooting tool. So that's kind of all over the entire platform in a nutshell. So we will go a little bit into knock model that we kind of look at. We have seen this happen over and over again in our customers networks, in our own knocks, we see multiple console scatter context across various different things. We see customers, I have done it myself, log into multiple different, try to figure

things out, you know, stitch everything manually. However, the whole point of cloud control is the power of one, which is you create, you have one platform at correlated context across everything. So that that is the specific reason for kind of building this platform. So not to time on the slide, but it's just to provide that contact where we are coming from. And what we're trying to do is make sure that we can surface all of the relevant information in the customer.

[00:10:44] Speaker2:
So primarily I'm hoping the slides are showing up. So if you look at cloud control, cloud control is divided in three major buckets. On the right hand side, what you're seeing is Cisco Unified Identity. The Cisco Unified Identity is, as I said, the author and the odzy, which binds the identity of a user into the platform. On the top, what you're seeing is primarily the, and I've not gone too much detail into it, but try to keep it a little bit high level. It's primarily the engine behind Cloud Control and Canvas. There are three major buckets. So the first one is the experience and the identity context. So when you log into Cloud Control for the first time, when you connect the tenant, when you're connecting your IDP, you're managing your users, all of that is provided by the experience and the identity context. So when you're doing RBAC, when you're what is seeing on the top nav, all of this is managed by this kind of the box on the left experience and I did. So we are running multiple microservices, right now we are on AWS, Cisco's AWS VPC and everything is guys we are running EKS, primarily a lot of the, a lot, all of our, all of our services is on EKS and we are using Kubernetes. We have a bunch of other things that we are using, but primarily allows us to scale very easily a lot of this elastic in nature because depending on scale we want to go up and down as well as go in-breath depending how much devices are coming on board. So the experience and identity context provides you with that information. So now that you've logged in the platform services that we're talking about particularly domain management, topology, unified inventory, search notifications. All of those contribute the second bucket of services that we are running and a lot of the databases are utilized here as well, particularly for inventory, which is more of a relational DB that we are using, mostly our Postgres, and then topology is a little bit more of blob use elastic search for it as well and some dynamo to make sure that we have elasticity again flexibility in finding things and connecting things. And then finally we have the AI services. AI services is where we have we talked a little bit about it in studio. We have AI gateway, agent orchestration, primarily what our canvas is using. Most of the data in AI services is actually real time. So when you actually make a query, the information is pulled. The only thing that we have in the back end is the network models or the LLNs which are running. We use, there are multiple contexts and I know Rajat will go deep into it. But primarily, there are two types. There are multiple models, I would say. There are two or three types of models and the models of purpose built for certain things. For example, the Cisco network model it's primarily for deep troubleshooting, for reasoning. We are also using some frontier models today to do very quick kind of responses in Canvas. Again, we'll go deep into that, but those are to provide certain context services. So those are the things that is kind of running in the back end, powering the platform. Now, the orange that you're seeing, the product integrations part inside the architecture provides primarily four major things. So I'm going top down here, but the product integration element provides with the API and the MCB context. And this is super important. The MCB context allows not only the platform to connect to

Cisco controllers, but if there are other, for example, that's why the integration and the third party context is becoming a little bit more easier for us because if there is tools which are opening up MCPs towards the platform, we can pull data there, including third-party services. We are looking at Splunk and Thousand Eyes and IQ for third-party today, but for example, if there is CMDB like ServiceNow and they provide the MCP, we can pull from there. So again, by taking advantage of this technologies, we can actually now kind of connect and take, I would say, ingest data in a much easier fashion than before, actually. So the API NCV context provides that connectivity, token exchange is utilized for, again, exchanges this tokens for the identity context. We collect event and logs. We also generate event and logs. Primarily, these are used by our, not just engineering, but also tag teams to if something does go wrong while if they want to troubleshoot. So we have audit logs as well as a lot of the system logs available for our troubleshooting teams. And then we also have security services. Security services is beyond our work. So these are actually running, making sure data at rest and data in transit are fully encrypted. We are adhering to very strict protocols, particularly since data is going to be traveling between on-prem and cloud. And also we will have devices connected in this controllers will have issues and so alerts coming in. So we need tenant isolation. We need to make sure that all the data is very, very secure. So the security services are utilized for that. And then below, of course, we have all the on-premise and the cloud products provides information in this data. There is a down arrow which says receive federated actions right now. The only federated action is or Z kind of a request. We will, there are certain exceptions to that. We will talk about it, but write back generally is not there today. We are working through that when we, so right now the system operates more as an aggregation visibility layer as well as an agentic ops layer. We don't write back into the network

[00:17:08] Speaker1:
at this point of time, right?

[00:17:09] Speaker2:
But we do have the pipe as we evolve this platform in the future.

[00:17:17] Speaker2:
So what I'm gonna do now is while I have all the slides, but I'll take you through the demo rather than through the slides. So what I'm gonna take you through is we'll talk about the login, we'll talk about a bit of RBAC, which kind of, we will see how RBAC operates within the platform. We'll talk about unified inventory and how all of this information is correlated and how we generate insights within inventory. Then we'll talk about primarily topology, the end-to-end topology and how topology is actually available and then alerts and notifications. And then from that point onward, we will actually jump into Canvas and then Reset

[00:18:05] Speaker1:
will take over. So let me go ahead and share very quickly the demo.

[00:18:21] Speaker2:
All right, so like Marcus mentioned, please familiarize yourself with the D-Cloud. We are all using D-Cloud for all our demos. D-Cloud is sort of here with us has been instrumental working with the D-Cloud team, particularly with Dustin to

bring this up. It's fully production ready. All our whatever you see in production is available in D-Cloud. It has a full backend with multiple things connected, and I'll show you what things are connected because that is the first use case. You are coming into Cloud Control for being the front door into Cisco's product portfolio and in DCloud, all of these products are already connected. So we have Veracruz, Interstate Hyperfabric, Security, Pram, Thousand Eyes, and Nexus Dashboard and IQ, everything integrated into the DCloud instance. So if you come into DCloud, you will be able to play with all of them. So the primary point here is that whenever you click, you automatically launch into that controller without having to do another login. So that's primarily benefit of, again, we're talking about the token exchange part of it, the CUI part of it. So it allows you to log it. Okay. Then primarily we've talked about a few things. So before I go into the each of, I just want to talk about RBAC a little bit. So you can see users are very easily managed here. We have a bunch of users. When you add a user, for example, in Cloud Control, you provide an email. The email will automatically be resolved by the IDP that you have connected. You can see here, you can connect multiple things. You can connect your tenants, domains, and identity providers. Once the identity provider is connected, you provide an email. For example, in this case, I can just put my email here. And if I click Next, it will say the user details are found because it's connected to Cisco IDP. And when you click Next, I can now select a role. So this was the very point of showing this. There are three roles available. We have Tenantful Admin, Tenantread-Only Admin, and an Integration Admin. The Tenantful Admin obviously has access to everything. The Tenantread-Only Admin can see everything and then integration admin are the ones who can actually connect various pieces, things, other things into cloud control, right? But these are the kind of the roles that comes out of the box. It's important to provide Tenantful admin to only a few people because you get access to all the data which is coming. But generally, the Tenantread-only admin is good primarily for L1 companies and we'll show how from a Canvas perspective. One of the things to kind of think about a little bit is that we are adding, because the context is across the network and we know that our customers may have different teams. It's important that the customer understands that the access to these different parts of the network needs to be provided, at least for L1 as a lead only so that Canvas can be utilized. The AI part of the system can be fully utilized because we honor the RBAC in the controller. So if you don't have access to it

[00:21:39] Speaker1:
and you're trying to troubleshoot,

[00:21:41] Speaker2:
you'll not be able to get full access to it. So there is a balance to that, obviously. You could have L1 as full read only and as you go up, the RBAC actually collapses and becomes more in-depth, but having access to a different system is becoming a bit more critical because that's how you can actually learn and get more data about AI pieces. But there is good thing about that. Even if you don't have access to it, Canvas does allow you to invite users into your dashboard and Rajat will show us that. But it's an easier way. But if you do have access, the troubleshooting becomes much faster. Anyway, so our back is important because the system, all of the context, whatever you can access, whatever you can run on is dependent on this context. So I'm going to get out of this one and so, okay. So now

very quickly, I'll take you through three of the platform services. So the one being inventory. Inventory is fully AI powered. So what I mean by that, so couple of things. One, we all know about an inventory table, but this table is completely enabled by AI search. So you can run NLP on this rather than standard Regist query. There are multiple filters which are available that you can also select and you can check for as you are trying to sort the table through. But one of the things that you will see here is that this is a fully, I would say,

[00:23:19] Speaker1:
a table with primary movement,

[00:23:21] Speaker2:
all of the controllers are sending all of the data, right? So the sources are everything. So you can see next is that World Web X of fabric in the site. Every single controller which is connected is sending inventory information to us and that is what inventory is shown. And then we also have AI sites on top of the data that is coming to us. The cards that you are seeing, we are not crunching the numbers, but this is coming from the controllers. Controllers send us this information, we correlate. So for example, active network animal is need investigation. this card with we see that there are anomalies because the controllers are telling anomalies what the intelligence we use this if the animal if the anomalies are the same and in this case whatever you're seeing 23 from Nexus dashboard 9 from hyper fabric 5 from Intel in the side are all afflicted with the same animal so when you look at that device will go ahead and filter There are many other insights which are available that you can go ahead, they are color coded based on severity, red is obviously more severe than orange or blue, but we continuously are generating these insights from inventory. The other thing about inventory primarily is that you get a lot of visibility, one One of the good things that I like is the asset class mix. It's like a mini-CMDB inside of the platform. You get to see about everything within like the entire estate very easily have more complex queries in a CMDB anymore. If it is under controller control and cloud control can see it, we will report it, right? So it's a very easy way to look at it. Now there are various other things within inventory cannot go into all of them due to time, but please do log into dCloud, play with this, and provide feedback that will be very valuable for us. Then the next one I'll very quickly show is topology. As I mentioned, topology is again end-to-end. We are looking at physical and L2 links. Everything that you are seeing here is live. All of the links here are SDYN, live links take multiple sites across the board. across the board. The left panel that you can see here is dynamic. So as you change views within the topology, the left panel will change. So for example, right now if I go into Mexico City here and I go into topology, you can see that the panel changes now into Mexico City providing information about any devices on any issues within that site. You can go ahead and you can look into the topology with a much more granular look. And as soon as you go into a site construct, the topology changes to a much more physical view. And this is how exactly it is kind of connected, right? This is, and when you go and click on any of the elements, for example, For example, you will get information on how they are connected, which devices are connected where, and all of this information right now is actually coming from three different controllers. So we are getting the firewall information coming from SCC. We are getting some of them from Cloud One and a lot of the wireless coming from M4. Actually, this data is coming from three different places

which is being stitched together. you know, just please do keep in mind. We provide information about pretty much all devices, so it's not tied to just campus, but this is a very quick example that I wanted to show. But we are collecting all the data and showing all the data from a technology perspective. Again, you can go back and forth from topology and inventory. So for example, if I click back, it will take me back into inventory and provide me with information about that device

[00:27:36] Speaker1:
that I had just clicked on.

[00:27:37] Speaker2:
There is a lot of metadata, you can also do product, which means if you click open in product, it will take you to SCC and provide you with the information about that specific FTV

[00:27:49] Speaker1:
that I had clicked on.

[00:27:51] Speaker2:
And the final thing that I wanted to show from a platform service perspective is primarily the adults. So let me cancel, move. So what we have is Action Center and this is where all the alerts are coming from all our controllers. We make sure that we correlate all the alerts if the same alert is coming from the same controller. We correlated make sure that we show you one single place where everything is there. And this is one of the places where we jump off to Canvas. So Canvas can be automatically enabled. You can create a new Canvas, but generally we are seeing a lot of the utilization is coming from actions. There's a lot of other things to talk about. Unfortunately, we are a little bit short on time. We have only one hour. So please play with the Cloud and we'll also have some call to actions for you. So with that, I'm going to hand it over to Rajat, who is going to take us through Canvas. Rajat, all yours. Thank you.

[00:28:59] Speaker1:
Awesome. Thanks, Amit. thanks for the really good introduction. So what I want to do is I actually wanted to start off with you know just an overview of Canvas and Assistant. So you know I'm in the same DeCloud instance, I think we posted the link in your chat so you should have that. So I'm in the same DeCloud instance and you see you have the Assistant and the Canvas here. Now I think most of you you are aware of this, but the assistant and the canvas share a common backend. So I'll show the architecture in a bit, but the AI gateway that various MCP servers or agents use for registering their tools and skills, it's a common backend. The difference between assistant and canvas is, assistant is more chat style. It's more for single-term conversations, whereas canvas is for more complex from the shooting, and then Assistant is a single user tool. So, and Assistant is private to one individual, whereas Canvas can be shared across individuals. Now, you see Assistant and Canvas here, but I just wanna really quickly show you. The Assistant and Canvas is, you know, I'm right now, I just switched to the Nexus dashboard, and you see this Assistant and Canvas here as well. And the idea here is you could start off their conversation or a, you know, a investigation in the assistant, in the Nexus dashboard, it'll

[00:30:30] Speaker2:
get aware, it'll be aware of the page that you're on, it'll have some page context, user

[00:30:33] Speaker1:
context, and that same conversation carries you, carries with you or you can carry it with you as you go to Cisco Cloud Control. Not only Cisco Cloud Control, as you go to any of the integrated products within your Cisco Cloud Control, that same thread is available with you as you go across all of this. And then obviously once you go to Cisco Cloud Control, you have that here in the Assistant and you can see those threads will actually follow you and all those threads are here right here with you in the Assistant. Now what you can do is once you do an investigation and you see it's a little more involved and you want a larger screen, if you will, or an infinite board to actually carry that investigation out, that's when you go into Canvas. And of course, you can then invite folks to that particular Canvas that you're doing. Now, I just launched into Canvas and you saw that there's some quick start boards. So these are boards for just health and availability, wireless, van health, data center and computer operations, security policy and access, and discovery and inventory. So these are kind of boards that have predefined set of prompts that you can already start off with by asking you know you click on that board five or six prompts will prompts will just get queued and you can start asking those prompts but what you can also do is you can actually start an absolutely new canvas so you know you can come here you can start a new canvas and you see you land up in this board right in this canvas board and you have that same kind of you know prompts here, right? So you can see health and availability, what is the overall health of my Maraki organization, you know, gets running for you, showing you the routing, it's taking you to, you know, your network intelligence router, and you can see immediately it produced that card for your Maraki health. So essentially what you can do is you can start from either one of those boards or the cards. The other way to start, and I think I've it spoke to this was through actions. So in actions what you'll see is, you know, in some cases there's a single notification that's in actions and in some cases there's more than one like related alerts when they're related in time, they actually put together in the same site and you can actually go and collaborate in Canvas right here, right? So you can say, hey I want to collaborate in Canvas because I think, you know, there's something happening here. And for example, I'm only a network operator, and I probably need a data center admin as well to collaborate with to try and find out is the problem on the access side or is it on the data center side. Or potentially I also need, you know, an SD van or a thousand eyes administrator to try and find out if that's where the problem is. So you can actually go and collaborate in Canvas. The other thing that I just want to show you is, you know, in the home screen you actually see this prompt here it's kind of like the Google type search bar this is the assistant search bar as well so anything that you ask here is also connected to the same backend that you have in the assistant and in Canvas so you can start a thread from here you can certainly start it you know from by clicking on the assistant here or you can start it in Canvas and that's it that's how you actually go go ahead and do an investigation So I'm going to now quickly show you a little more around some of the things that you can do in Canvas. So when you start off in Canvas, a couple of things you want to know. You have everything here in terms of topology, in terms of

performance, incidents and anomalies. So I could go into topology and say, show me my SD-WAN VPN topology. It's again going to reach out to a topology agent. I'll show you in the architecture how that actually happens. So we start with a topology agent and it actually pulled up the SDVAM topology for you. Now, this is a live view, right? So it's not static. You can actually go and see, you know, Stockholm, Singapore. You can actually see where all of this is happening. And you can actually then also see that, hey, you know what? There are some issues here. I can go ahead and investigate these issues in this place. So that's certainly one way to do it. But let's assume that you don't have access to this. someone just sent you a screenshot off a outage. And so let me take a screenshot of this for you, right? So you capture this in a document and let's say somebody sent that to you. So you can actually come here and you can say, hey, add an image or a file, right? And I'm gonna go to my documents and I'm gonna go to that screenshot that I just created. I'm gonna add that. And you see it's upload the screenshot And I could say investigate this for me, very chat style, right? And if I can actually spell investigate, that'll be great. And you'll see it'll immediately go ahead and start investigating everything that's happening in that environment. It's not to the Canvas agent. So you have multiple ways of actually investigating things. You can also include knowledge bases. So a lot of enterprises have their own run books, right? They have policies, they have network standards. All of those can be actually put in right here through knowledge bases. And of course, then you have prompts that you could have saved, et cetera. The other thing I wanna show you is the modes of operation. So we spoke about this a little earlier. There is a default mode that provides you answers right away. And then there's a reasoning mode for more complex queries. And what the reasoning mode really does is it actually produces a plan for you. And it asks you to approve that plan. Once you approve that plan, it actually goes and does the collection of the data in multiple steps, and potentially the output of one of the steps will become an input for the other step. So the reasoning mode actually does a lot more conversations or it just doesn't go once and get the data. It'll go multiple times and it'll actually go and find out the data for you, go multiple steps and do that for you. So this is something that's also available for you. We have in the future, you know, the potential of doing a auto mode where you let the intelligence of Canvas decide whether it should go to the answer right away or the complex queries. But I mean, for now, we are asking the user to select one mode of the or the other. All right. And then finally, I want to go here to the share button. So, you know, you can actually see that you can invite the collaborators to your Canvas through the share button. So anything that you do in Canvas, even though all of these products are connected to Cisco Cloud Control, and Canvas has access to those, but the responses of Canvas will be restricted to the role and the access level of the user. And what I mean by that is, let's assume I am a Meraki administrator, right? The Meraki administrator will only be able to ask questions around the Meraki network, or I guess you can ask questions for anything, but access for that user is based or specific only to the Meraki network. And so what's gonna happen is, if they're trying to say troubleshoot an application access issue, they're gonna ask a Meraki, they're gonna ask a question, it's only gonna respond with Meraki, but if they wanna invite others, for example, a data center admin, that's when you actually go and invite the data center admin and the data center admin will then come and be able to ask questions around data center and then the board get populated with that. And so all of this then allows the user to actually go ahead and do multi-domain and multiplayer investigations. And then

finally, you can actually go and create a report. You can export as PDF, a particular card, or you can actually do it for the entire board. So you can generate a summary for the entire board. You can stack the cards, You can do auto layout. You can add images. You can annotate texts. You can lock some cards. If you say, you know what, this card is locked. I don't want this to be deleted, etc., etc. So there's a lot of things that you can do here. This is a limitless board. Potentially, you can have 50, 100, 200 cards here. Obviously, it depends on how much you want to investigate. The last thing I'll say about these cards is these cards are being produced on the fly. And what I mean by that is this is making use of generative UI and generative UI essentially is, you know, as the agent launches the investigation, reaches out to the product, gets data back. That data is then analyzed by what we call the widget agent and the response agent. And it looks at, hey, should I produce only text for this? Should I produce text annotable? Or should I produce text table card? you see that there's a topology here, there's a table here, what should I produce? And it does so on the fly. It generates the UI on the fly. So potentially you may not have this view anywhere in any dashboard, but it's been produced here because of the shape of the data and the amount of data that was returned to the user. And so that's how you can actually see that we generate UI on the fly for you. So it's quite possible that you ask the same question you know, one week apart and you'll see a different view, you'll potentially even see, you know, a different modality of that view. For example, if there are no outages that might just show you had their own outages, right? Here's the topology, everything's green, you know, you'll see absolutely nothing, but if there are outages that might go and, you know, highlight those for you. So this is not deterministic because this is actually generating it on the fly. All right, so this was a really quick demo of AI Canvas and DeCloud. I'm actually using the DeCloud instance that is available to everybody within Cisco. So I think in the Q&A, we've posted the DeCloud link. You can actually go there and do everything that I did. Everything is absolutely available to you. So please go ahead, get yourself familiar with everything that is here, and use this for pitching Cisco Cloud Control and AI Canvas to your prospects. One last thing I'll speak to before I actually jump to the slides and show you a little bit of the architecture because I know all the ICs are very, very keen on how does this work. One last thing I'll say is that you do not need to do any extra steps to integrate AI Canvas with any of the products. So basically, as in when you bring a product and integrate it into Cisco Cloud Control, AI Canvas inherits that integration. Now, there are few nuances. Like for example, you see Cisco IQ here, right? Cisco IQ is not yet integrated into AI Canvas. In fact, even I would argue for Cisco Cloud Control, Cisco IQ is more like a cross launch. It's not really fully integrated, not discovering inventory, all of that is coming. But as these integrations come into Cisco Cloud Control, all of the others that you see here, Meraki, InterSight, Cisco Hyper Fabric, through security, you've got secure access, you've got secure firewall, the cloud delivered FMC, You've got SD-WAN, Cisco Managed Cloud Delivered SD-WAN, Catalyst SD-WAN coming through security. That's all available to Collaboration Control Hub, Thousand Eyes, Nexus Dashboard. All of these integrations, as they come to Cisco Cloud Control, AI Canvas inherits those, and it has access to those MCP servers. So a user does not need to stand up any new APIs, do any more connections, new connections, doesn't need to stand up the MCP servers. This is all seamless for the user. All right, with that I'm just gonna quickly go and jump back into slide mode because I wanna speak a little bit to the architecture of AI Canvas because I know all the SES on the call are really keen on understanding

how does this work. So if you think about, let me turn this off, give me a second, okay. So if you think about the AI Canvas architecture, the part of it or the nucleus of this is the AI Canvas Orchestrator, right? And that's why I have a deep dive slide on the orchestrator. So when you input a prompt, the orchestration agent actually receives that, it selects the right agents, it defines the scope. There's actually a semantic agent that breaks your prompt down into individual tasks. And then it goes ahead and launches it into this manifest of specialized agents. And you saw some of this, right? When I asked a topology question and went to the topology agent, there's a security agent, there's a wireless agent, blah, blah, blah, there's a docs agent. We'll actually go and give you documentation. So that happens when you're in the default mode. In the reasoning mode, what happens is the reasoning mode acts like a deep agent. So it actually takes your prompt and it breaks it down and it actually discovers all of the tools and all of the skills that have actually been already loaded up into the system. And then it actually provides you a stepwise, plan or phase plan of actually executing that. And then it goes and does that for you. Now, obviously on the right, see that we have all of the Cisco products, but through Cloud Control Studio, we will have access to third-party MCP servers and agents. For those of you who saw the keynote at Cisco Live, we announced Agent Builder, and there are already 56 vendors, and the big names are all there, the three hyperscalers, AWS, Azure, GCP, ServiceNow, Jira, Infoblox, NetBrain, And they're all there. They've all signed contracts with us already. 56 of them have already signed contracts with us to code develop agents and provide MCP servers that we will then register in our own AI gateway. And so Canvas would be able to now respond for Cisco infrastructure, right? Through what I just showed you. And for third-party infrastructure or third-party services, if you will, CMDBs, ticketing agents, et cetera, through that entire ecosystem. So really, really valuable. We heard loud and clear that, you know, and notices go only shop. And that's where this Cloud Control Studio is coming in. So really quick, I know I'm gonna run out of time, so I'm gonna go a little quick. So here you see, you know, there's a developer piece. This is where we have Cloud Control Studio playing, but an end user can actually come in and the orchestration agent has a supervisory agent that can either go in the React mode, which is the default mode or the plan and execute mode, which is the reasoning mode and does dynamic planning. And then the executor agent actually sends it down to the AI gateway. And that's where you see you have the entire registry, MCP server registry, as well as the agents registry. Now the agents registry is likely future looking where we support the A to A protocol. For now we're supporting only the MCP protocol. So is the MCP server registry that you register your MCP tools. even if there's an agent at the back end, you wrap it around your MCP tools and you register it there. And that's where you launch your queries

[00:45:55] Speaker1:
to the underlying products, get the data back and then present it through some of your core services. And you see here there's a Canvas board manager, there's collaborative services, there's observability stack services. And so this is kind of like an overview of the architecture. So really quickly, what can Canvas do? So you can see I've listed all the products here and this is gonna be available to you. And these are the services that have been exposed by the underlying products to Canvas. So let me just take Secure Firewall for example. Secure Firewall right now is exposed side to side VPN tunnel status, VPN diagnostics. They have focused on VPN

initially, but you'll see on a rolling basis, more and more skills will start or tools will start getting registered with the AI gateway. for example, inventory, policy discovery. So my main kind of Uber point here is today, not everything that is available in the dashboard is available in the iCanvas. Now that is irritating. I know it's a bit of a irritant for users when they go and try and ask Canvas something and Canvas says I don't have access to this data. But as we march towards general availability in the first quarter of FY 27, you'll see all of these product teams will register more and more tools with AI Canvas. And so the not start or the intention is if you can do something in the dashboard, you can actually do it through AI Canvas. And then of course you can do a lot more, you can do cross domain. So I actually already showed you this workspace, so I'm gonna skip over this. I'm gonna show you the value candidly of cross domain analysis. So if you see here, you know, why is my finance apps low? The problem could be networking, it could be a security issue, it could be the data center, or you could actually just go to observability through ThousandEyes or observability cloud through Splunk and try and find out why is the finance apps low, right? So for each one of these questions that you ask, a user does not even actually need to know where the problem lies, which domain that problem lies in. Just think about this for a moment, right? Like invariably, we had domain experts or domain admins that would go and investigate their domain. But now a user, imagine if they have access to all domains, they could actually come and ask a very, very open and a question, like for example, why is the Chicago branch not able to reach internal apps? Or why are my users having problems reaching Salesforce? And it'll actually go across your entire digital stack and try and find out where the problem is, right? Very, very powerful cross-domain tool. All right. With that I think for the last kind of five minutes I want to quickly touch upon the roadmap of where we are and what's coming next because this is going to be important I just want to caveat here you know we have just gone through Cisco live and everything that our engineering teams had committed to was delivered at Cisco live so you'll see that in the slide and we'll speak about future you know I saw a lot of questions in the chat about Catalyst Center and about and about Cisco IQ. So this is where we'll speak about those, but these can change. We've not yet gone through a joint commit with those teams. This is intentional. This is kind of forward-looking, but we want to share this with you because we want to arm you with that data to be able to provide back to your users when they ask you about, you know, what about this? What about that? So the first thing we'll just say is controlled availability was announced at Cisco LiveUS and you see all the products there. You know, I'm not going to drain the slide, but you can see all the products that are integrated there. The region is U.S. only, right? And we have a number of certifications, SOC2 type II and ISO 27001 are the first ones that are going to actually come. And all those services are available. What we're aiming for for the first quarter of FY 27 is actually a general availability, where Splunk Cloud, right, is going to become a first-class citizen. And the intention is to bring it with not only Splunk Cloud but even Splunk Observability Cloud as well as ITSI to bring them into the AI Canvas and Cisco Cloud Control AI ecosystem. The identity fabric which is Identity Services Engine and Cisco Identity Intelligence is probably slightly further out in Q1 or potentially even Q2. Like I said this is forward-facing but we certainly want to give you this view. Slightly further out Splunk will come earlier but this is the way we are actually looking at doing it. And the other thing that's also going to happen is Catalyst Center. I know this is absolutely essential for everyone. So Catalyst Center today, you can register

Catalyst Center through the Meraki Global Overview and can register it with Cisco Cloud Control. In fact, some of the inventory items that you saw in DCloud was coming through that manner, but we're going to simplify the onboarding tremendously. And AI Canvas will also start supporting Catalyst Center. So you could ask queries today if you ask queries about your access network, your campus branch, et cetera. It is only reaching out to the Meraki network because that's all it has access to. But AI Canvas will also get supported in the first quarter of FY 27. What's also going to come is multi-tenant mapping. This is extremely important. So today, within one tenant group of Cisco Cloud Control, which is where you see the boundaries for your inventory, topology or AI Canvas operates within one tenant group. Within one tenant group, you can only bring one instance of a product. So for example, you can only bring one Meraki organization tenant. You can only bring one inter-site instance, etc. What we'll allow in the future is multiple Meraki tenants and multiple instances of other products coming in, what we're calling the one-to-many mapping. So that's going to come. The Q3 and Q4 is a little further out, so I won't drain that, but you can see we've got Splunk Enterprise Security on-prem SD-WAN and all those Cisco cross-work etc available as well as regional expansion starting with Frankfurt in Sydney and then going on to Tokyo and Mumbai India. Anything to add there, Amit, on the roadmap? No, I think you covered it all. This is great. Awesome, fantastic. We are three minutes out, I do want to provide a little bit of a view on, you know, the more forward-looking Cloud Control Studio, which was announced at Cisco Live, and you'll see it'll start coming into Alpha and Beta. The aim is for Beta in the first half of Q1 of FY27, so August-September timeframe. And Cloud Control Studio will have three components. I'm showing two components here, which are the developer tools, agent builder and app builder. Agent builder is for building and designing agents. Now, it's a little bit of a misnomer. Agent builder is also going to allow users to bring their own agents. So for example, if they've already designed agents in their own platforms or, you know, they've subscribed to third-party agents, they'll be able to bring those agents and register the tools and skills of those agents with our gateway, as well as is then have the AI canvas respond with tools from there. And then the app builders to actually build app using a OpenAI Codex to build apps on the platform. I spoke to this. There are 50 vendors. The slide is going to be available to you that have already signed on. In fact, 56 I think to be fair. And they've already signed on. And we will continue to expand the footprint. The idea is to try and expand the reach of Cisco Cloud control and AI canvas to the entire digital footprint of customers. And then the next kind of thing I want to touch on is this compliance agent. So we're working on a deep agent called a compliance agent. Oftentimes, we hear about, hey, I want to know, are there any piece outs in my organization? Assess my vulnerabilities and recommend any compensating controls or where patches are available. So the compliance agent was also announced at Cisco Live US, but you'll see over the next quarter or two, will bring a compliance agent to run compliance checks on your Cisco and third-party network as required. And then the last thing I'll leave you with is the models. So today AI Canvas uses both frontier models as well as Cisco domain models. Today we have the deep network model. You may have heard of it as DNM. We use the deep network model for deep network troubleshooting because, standardly, nobody has better information about network troubleshooting than we do. And we've trained that model, things been in V21 now, 20 iterations of training that model based on all of that data. So really it does networking better than any other Frontier model can. But there are still some tasks that Frontier models can do better than a deep

network model, especially if it's not a network troubleshooting task. So we send the data or we send the query to both kind of like deep network model and Frontier model as needed. But you'll see in the future, we'll start leaning more and more on our own proprietary models. We are working on, you know, secure deep security models, deep application models. We'll start leaning more and more heavily on our own proprietary models and less on, you know, the deep models itself. All right. So finally, call to action and resources. Call to action. Please tell your customers to log on to cloud.sysco.com. It's very simple. Cisco Cloud Control is available to cloud.sysco.com. They'll see a request form there. They can fill the request form out, and that request form goes into our queue because we are in control of availability right now. We're controlling the pipeline for enabling Cisco Cloud Control for the customers who are signing on. I think we already have close to what I think as of yesterday was about 1,567 customers that have signed on for Cisco Cloud Control. We'll be opening the flood gates slow and steady, but obviously as when we go to general availability, Anybody is going to be able to self-serve onto Cisco Cloud Control. But please tell your customers to sign on to Cisco Cloud Control and register for their interest to get Cisco Cloud Control and control availability. And finally, some resources for you, the decloud demo instance that I used and even I met used for the demos. Sales Connect, really, really good resources. I think the marketing team has just outdone themselves. I really like the amount of detail that they've included in the BDM-TDM. you actually have gifts that you can see how the operations happen. There's the AC Champion SharePoint, Charles Duffy and team have done an awesome job of putting that SharePoint together and there's a WebEx Ask Suspoke Now Control channel. And with that, I think we're one minute over. I'm gonna pass it back to the host.
