[00:00:03] Speaker1:
So I think we talked really, you know, we give an overview about your, your aggregated hardware assets and overview about how everything's actually connected. I want to talk about the next thing, which is really where a good number of, you know, admins are actually starting off with, which is going to be actions. So most people, they, they don't, they want to go ahead and start off with an issue that has been reported somewhere either with a platform controller or of course we also know service now for ITSM. But importantly, from a platform controller, we all know that every single one of our hardware controllers or platform controllers are sending alerts, right? There's some sort of issues that's able to report, whether it's going to be critical, like severe, medium, critical, whatever it is, right? And the cool part about all this is that every single one of these platform controllers is sending alerts to Cisco cloud control. And what happens with Cisco cloud control is that we're actually aggregating related alerts together and forming something called actions so that we're able to see an aggregated view across every single one of these hardware controllers. Now the thing about it is that I'm sure we're all here about this time and time again. I'm sure you witnessed this Lila and the concept I'm about to talk about is alert fatigue, right? We hear about us time and time again. I'm getting hundreds and not thousands of alerts from all my different sites. And I don't even know where to start at this point. You know, in the past minute, I got just 20 of them. What do I do? So, you know, the cool part about all this is that cloud control helps to solve this directly for you. Now, as you can see right here, I'm going to click on just a random one right now. Look at this. I'm able to see that from Nexus dashboard, there are, I don't know how many are right here, right? One, two, three, four, five, like so many of them just happening within the span of four minutes. And you can see it says bgp pure connection down and it's been reporting for a number of different IP addresses right here. So cloud control as you can see actually brings them all together says, Hey, this is these are related and gives you a symptom right here that tells you exactly what's happening for all these different related alerts. And the cool part beyond that is that it immediately starts to trigger the AI assistant, which is utilizing the same backend as canvas to start investigating the problem to help you understand recommendations for the next

steps of what to do here. So instead of having to go into the dashboard.

[00:02:25] Speaker2:
One of the things that I want to make sure we highlight is that we are receiving these alarms from all the platforms that are onboarded in Cisco Cloud Control. So it's one place for us to aggregate this information. In the past, we needed to go to Moraki dashboard and then IntraSide and the Nexus dashboard and Catalyst Central now everything is in one place. We never had that before. So this is the power of one of the powers I would say of Cisco Cloud Control and bringing all these domains together.

[00:02:58] Speaker1:
Exactly. The intent ultimately is to not just aggregate for one product but for multiple that are related as well. So the ultimately you can just really see, get a cross product, cross domain experience across the board and really simplify having to do exactly what Lila is saying like going to multiple products to find the issues and find where the correlations at.

[00:03:18] Speaker2:
And right now, if you go to the, you see in the left-hand side, the first ones they say they come from Nexo's dashboard and then we have alarms that are from Maraki, the three at the bottom. So we are getting all this information from the different controllers. The one thing a little bit, the elephant in the room and we need to have this in the back of our minds is that, yes, in this particular deep cloud environment, we have a ton of alarms. And the reason for that is that no one is solving the problems. In real life, you will not see all these alarms here. In these environments, we are continuing generating problems and alarms. In real life, those actions would have been resolved. So things are resolved, and we clean them up in DCloud. We don't, so that you have them for demo purposes. So if you get that question from the answer, that's the reason. Demo environment, all these actions on purpose. We are generating them on purpose. and not be resolving them on purpose.

[00:04:17] Speaker1:
Yeah, exactly. But you can mention though that, hey, you know, in Cloud Control there's an entire process for you to be able to assign it to somebody as like one of the higher level admins of Cloud Control. I'm gonna assign it to somebody else to go solve the problem. And they can go in, for example, market has resolved, right, market has dismissed. right? Depending on what the evaluation is after you gone ahead and done a little bit of troubleshooting. So there is that whole aspect of alert management that you're able to do directly

[00:04:43] Speaker2:
here inside of cloud control as well. Exactly. And that's how we expect it to be used in real life, but you know, in demo environment, no one is cleaning up these things or properly disnessing or resolving the issues. Exactly. Going back to our original action from Nexus

[00:05:00] Speaker1:
dashboard, you're able to see that our output from the assistant actually came back and it's providing us with analysis. But you know what, beyond being able to

see this analysis and some additional information that it was able to get from in this case, the Nexus dashboard agent, we can even click on collaborating canvas to bring this over to a collaborative multi space, a multi player workspace. And as you can see, as you can see the entire assistant chat has gone over here. So for example, I just take a look at the actual content here, right? it's able to go ahead and do some additional deep dive to understand what exactly is an issue with the multiple bgb peer connection failures across these different devices. So it tells you that analysis right here. And that's what you want to talk about with the audience that it tells you what kind of evidence is able to get from Nexus dashboard because one of the paradigms that we always mention when it comes to canvas is that it's not a black box experience. We'll never just tell you a recommendation or next step without telling you why we're thinking this way.

[00:05:55] Speaker2:
One quick thing. So for people demoing, I hope you realize the flow. So Richard was in action, so that came proactively from the controller. He was able to look at an action, got some information from there. We are launching in Canvas and all the information that was part of the alarm and the analysis is auto-populated. None of these he prompted anything manually. we went from one to the other automatically and what I like is that he has a chat window expanded. So again, from a demo perspective, I would recommend you do the same thing because it shows better when you have the chat window a little bit more open. So that flow, it's a very good flow to use in your demos. Sorry, go, go continue. No, absolutely. Those are incredibly good tips.

[00:06:48] Speaker1:
And I also want to make sure that everyone here calls it a very key thing, right? cams is all about deeper investigation. So make sure you're calling out exactly what is a problem that we're solving here and what's the next steps that it's recommending. So in this case, you could see that, Hey, we're, there's a, there's a, there's an insights able to figure out that there's a strong correlation with the interface down for, for these two particular interfaces. Right. And it says that, Hey, there's a correlation with BGB session drops. That's a big insight right here that's helping us to understand what exactly the problem may be coming from. And then we talk about, Hey, what are, what's the that's the blast radius right here, right? What are the things that are actually affected by that particular alerts that's being shown from Nexus dash or being sent from Nexus dashboard to cloud control that shows you all these different things. And then ultimately it tells you exactly what is going wrong and what you should be doing next to do is the actual effective troubleshooting. Now, beyond that, you'll also see that we have a paradigm now to make it so that the widgets are actually generated directly in the chat experience. And the reason why and how we can explain this is that we wanna make sure that you as a user are fully in control of your workspace. When it comes to these larger visualizations, we give you the option to see if you wanna actually share in the workspace, that common workspace where somebody else can see it as well, or if you feel like it maybe it's not something that is relevant to you at the time, you can continue to keep it in the chat. So that level of versatility and usability is completely there in Canvas, even just as of today. So this right here, overall is how actions works at a high level. We highly suggest you to go and make sure that you understand which ones you should want to select and, you know,

[00:08:23] Speaker2:
do a little bit of prep work

[00:08:24] Speaker1:
before any of your demos to customers, right? Make sure you really understand the flows. And I'm going to show you a number more and you're going to see how that prep work going into Canvas really is going to help you and making sure that your demo is just the best possible here in DCloud.

[00:08:38] Speaker2:
Rachel, you make a good point. So for myself, I always schedule like 30 minutes before each customer demo to log in into DCloud look what's going on at that time, look for the things. Most of the issues are constant, so you will find them, but I like to look and prepare so all the things that Richard is calling out that he preps beforehand, we strongly recommend that you do. That will make a more successful demo, so great call out.
